Nearly halfway through, I still didn't feel very connected to the characters or compelled to keep reading by their stories. While the language is beautiful, the prose keeps the characters at arms length. Dragonfly is a type of flying insects. There are over 5000 species of dragonflies that differ from each other by size, type of diet and habitat. They can be found on all continents except on the Antarctica. Most species of dragonflies live in tropical climate. Dragonflies usually inhabit areas near lakes, ponds and rivers because water plays important role in their life cycle. According to the latest scientific investigations, each 10th species of dragonflies is endangered. Female lays up to 800 eggs in the water. Eggs will turn into larvae that live in the water until the stage of adult insects. Adult dragonflies spend their life in the air. Dragonflies can survive from few weeks to couple of years, depending on the species. The dragonfly flies away over land. It only returns to the water to reproduce and continue this cycle. The life span ranges from about 6 months to over 7 years (most of it is spent in the nymph stage - the adult lives for only a few weeks). Classification: Kingdom Animalia; Phylum Arthropoda (arthropods); Class Insecta (insects); Order Odonata (dragonflies and damselflies); Suborder Anisoptera (dragonflies), many families, including Family Libellulidae (skimmers or pond dragonflies). There are over 5,000 species of dragonflies all over the world. Where Do Dragonflies Live? Dragonflies can be found all over the world. They typically stay close to water; most species of dragonfly spend the majority of their life underwater or close to the surface of the water. As nymphs, the dragonfly molts several times under the water. Molting is a process in which an insect sheds its exoskeleton to make room for new growth. The nymph eventually makes its way to the surface, where it stays and waits for its respiratory system to adjust to the air.
